The events involved in the establishment of a latent infection with *Mycobacterium tuberculosis* are not fully understood, but hypoxic conditions are generally believed to be the environment encountered by the pathogen in the central part of the granuloma. The present study was undertaken to provide insight into *M. tuberculosis* protein expression in in vitro latency models where oxygen is depleted. The response of *M. tuberculosis* to low-oxygen conditions was investigated in both cellular and extracellular proteins by metabolic labeling, two-dimensional electrophoresis, and protein signature peptide analysis by liquid chromatography-mass spectrometry. By peptide mass fingerprinting and immunodetection, five proteins more abundant under low-oxygen conditions were identified from several lysates of *M. tuberculosis*: Rv0569, Rv2031c (HspX), Rv2623, Rv2626c, and Rv3841 (BfrB). In *M. tuberculosis* culture filtrates, two additional proteins, Rv0363c (Fba) and Rv2780 (Ald), were found in increased amounts under oxygen limitation. These results extend our understanding of the hypoxic response in *M. tuberculosis* and potentially provide important insights into the physiology of the latent bacilli.
