Description of Model Design

Geometrical Parameters of Cellular Compartments

The total volume of the model cell (V_{cell}) was set to 20.9 pL. The fractional volumes of intracellular compartments (myoplasm 0.68, NSR 0.055, JSR 0.0042 and dyadic space $f_{\text{Ca,t}} \times 0.000032$) were adjusted to be consistent with the model of human ventricular epicardial myocyte published by Iyer *et al.* [5]. The total membrane area of $15,000 \mu\text{m}^2$ corresponds with the membrane capacitance of 150 pF. The dyadic space is described only at the t-tubules because of their major role in excitation-contraction coupling [50].

The total volume of the t-tubular system in the model cell represents the sum of the volumes of all t-tubules (their density in surface membrane was set to 0.19 per μm^2 [38]). To keep all geometric parameters of the model cell consistent with surface/volume ratios ($A_{\text{tot}}/V_{\text{cell}} = 0.72 \mu\text{m}^2/\mu\text{m}^3$, $A_{\text{tub}}/V_{\text{cell}} = 0.403 \mu\text{m}^2/\mu\text{m}^3$, $A_{\text{surf}}/V_{\text{cell}} = 0.327 \mu\text{m}^2/\mu\text{m}^3$), mean radius of the t-tubules (210 nm) and fractional area of t-tubular membrane (0.56) published by Ohler *et al.* [15], the fractional volume of t-tubular system must have been reduced from 0.0867 to 0.042 [15]. To simulate the ion gradient in t-tubular lumen, the system (“each t-tubule”) was partitioned into nine concentric cylindrical segments S_{t1} , $S_{t2}, \dots$, S_{t9} (Figure S1). To increase the accuracy of computation of ion concentration changes close to the t-tubular membrane, the volumes of segments S_{t1} – S_{t8} were set to 3% of the total tubular volume; further reduction did not significantly alter the results. The outer radius of each segment is listed in the table of Figure S1.

Figure S1. Schematic representation of part of the model t-tubule. The tubular lumen is partitioned into nine concentric cylindrical segments S_{t1} , $S_{t2}, \dots$, S_{t9} . Segments S_{t1} – S_{t8} (shown in grey) occupy 25.3 times smaller volume than the segment S_{t9} (white centre). The table shows the outer radii of individual tubular segments and their fractional volumes.

Membrane Currents

The description of principal membrane currents was modified to be consistent with recently published models of human cardiomyocytes. The formulations of I_{Na} , I_{Ca} and I_{K1} were adopted from Iyer *et al.* [5]. To describe I_{Kr} , I_{Ks} and I_{Kto} the simplified formulations published by Ten Tusscher *et al.* [4] were used. Other currents such as I_{NaCa} , I_{NaK} , I_{pCa} , I_{Naps} , $I_{K(Na)}$, $I_{ns(Ca)}$ and I_b remained unchanged [14] and I_{Kp} and $I_{K(ATP)}$ were omitted.

The maximum conductivities, current densities or permeabilities of ion transport systems (Table S1) were adopted from the above cited papers and, if needed, adjusted for the model to generate physiological configuration of APs as well as physiological levels of intracellular ion concentrations at rest and during activity [27–30]. An acceptable fit of the model simulations with experimental data of Li *et al.* [25] required also a slight reformulation of the steady-state voltage dependent inactivation of I_{Ca} (y_∞) as:

$$y_\infty = \frac{0.82}{1 + e^{(V_m + 28.5)/7.8}} + 0.1 \quad (1)$$

and of the time constant of I_{to} -inactivation (τ_s) as:

$$\tau_s = 0.085 e^{-(V_m + 45)^2 / 320} + \frac{0.005}{1 + e^{(V_m - 63)/5}} + 0.003 \quad (2)$$

Table S1. Maximum conductivity ($g_{X,max}$), current density ($I_{X,max}$) or permeability (P_x) of ion transport systems used in the model. The values are related to the total membrane area. $f_{X,t}$ represents the t-tubule fraction of the ion transporter underlying current I_X .

$I_{pCa,max}$	1.725 μA cm ⁻²	$f_{pCa,t}$	0.20

Because of the paucity of experimental data related to distribution of ion transporters between the surface and t-tubular membrane in human ventricular cells the t-tubular fractions of ion transporters related to currents I_{Na} , I_{Ca} , I_{K1} and I_{pCa} (Table S1) were preliminarily set to be consistent with guinea pig model [14]. T-tubular fractions of other transporters were set to 0.56 assuming their uniform distribution over the whole membrane.

Intracellular Ca^{2+} - Handling

The formulation of intracellular Ca^{2+} handling is based on the description used by Iyer *et al.* [5]. However, to prevent the intracellular Ca^{2+} overload and irregular Ca^{2+} release from JSR at higher stimulation rates, a readjustment of some parameters/constants was needed. It included: (i) increase of forward and reverse rate parameters of SR Ca^{2+} pump ($v_{\max f}$ and $v_{\max r}$) to 0.25 mM s^{-1} and 0.75 mM s^{-1} respectively; (ii) decrease of on- and off-rate constants controlling adaptation of RyR channels (K_c^+ and K_c^-) to 0.1 ms^{-1} and 0.0008 ms^{-1} respectively; (iii) increase of the time constant of Ca^{2+} transfer from NSR to JSR (τ_{tr}) to 20 ms; (iv) decrease of the time constant of Ca^{2+} transfer from the dyadic space into the cytosol (τ_{xfer}) to 18 ms.

Ion Exchange Between t-Tubular Segments and with the Extracellular Cleft Space

No data are currently available about the rate of ion diffusion within tubular lumen and between t-tubular and extracellular spaces. For this reason, the time constants controlling the ion exchange between cleft and t-tubular spaces are preliminarily adjusted to the same values as in guinea pig model, *i.e.*: $\tau_{\text{Ca,ct}} = 240 \text{ ms}$, $\tau_{\text{K,ct}} = \tau_{\text{Na,ct}} = 200 \text{ ms}$ [14].

The time constants controlling Ca^{2+} and K^+ exchange between the individual tubular segments were computed by multiplying the $\tau_{\text{Ca,ct}}$ and $\tau_{\text{K,ct}}$ by a factor taking into account the different diffusion area between individual segments and, in segments S_{i8} and S_{i9} , their different volumes. The resulting formulation is:

$$\tau_{X,St,n+1} = \tau_{X,extt} \cdot \frac{A_{base,n}}{A_{boundary,n}} \cdot \frac{V_{St,n+1}}{V_{St,n}} \quad (3)$$

where $\tau_{X,St,n+1}$ represents the time constant controlling the rate of diffusion of ion X from segment n to segment $n+1$ and the parameters $A_{base,n}$, $A_{boundary,n}$, $V_{St,n+1}$ and $V_{St,n}$ represent the area of segment n in the tubular mouth, area of the boundary between segments n and $n+1$, volume of segment $n+1$ and volume of segment n , respectively.

Because the concentration changes of tubular Na^+ are minimal, they are described in a single t-tubule compartment as in our guinea pig model [14].

Extracellular Cleft Space

Extracellular cleft space is described as a single compartment surrounding the model cell. The volume of this compartment (1.932 pl, 13.6% of total cytosolic volume) as well as the time constants controlling the rate of ion exchange between this compartment and bulk space ($\tau_{\text{Ca,bc}} = 24.7 \text{ s}$, $\tau_{\text{Na,bc}} = 14.3 \text{ s}$ and $\tau_{\text{K,bc}} = 10 \text{ s}$) were set to be consistent with the model of human atrial myocyte published by Nygren *et al.* [2]. The bulk concentrations of Ca^{2+} , Na^+ and K^+ were set to 2 mM, 140 mM and 5.4 mM, respectively.

Model Equations and Parameters

The basic units in which the equations were solved are: mV for membrane voltage, μA for membrane currents, mS for conductivities, ml s^{-1} for permeabilities, $\mu\text{mol s}^{-1}$ for ionic fluxes, mmol L^{-1} for ionic concentrations, ml for volumes and s for time. The suffix “x” stands for either surface (“s”) or t-tubular (“t”) membrane variables, and the suffix “o” correspondingly stands for ion concentrations either in intercellular cleft space (“c”) or in the first t-tubular segment (“t₁”). The physical constants and geometrical parameters of the model cell are specified in Tables S2 and S3, respectively.

Membrane Currents

The values of parameters and constants used in the description of membrane currents are listed in Tables S4 and S5.

Intracellular Ca²⁺ Handling

The values of parameters and constants used in the description of intracellular Ca²⁺ handling are listed in Tables S6 and S7.

Ca²⁺ Uptake From Cytoplasm Into NSR, J_{SRup}

$$J_{\text{SRup}} = K_{\text{SR}} \left(\frac{v_{\text{max}f} f_b - v_{\text{max}r} r_b}{1 + f_b + r_b} \right) \quad (109)$$

$$f_b = \left(\frac{[\text{Ca}^{2+}]_i}{K_{fb}} \right)^{N_{fb}} \quad (110)$$

$$r_b = \left(\frac{[\text{Ca}^{2+}]_{\text{NSR}}}{K_{rb}} \right)^{N_{rb}} \quad (111)$$

Ca²⁺ Transfer from NSR into JSR, J_{SRtr}

$$J_{\text{SRtr}} = \frac{[\text{Ca}^{2+}]_{\text{NSR}} - [\text{Ca}^{2+}]_{\text{JSR}}}{\tau_{\text{tr}}} \quad (112)$$

Ca²⁺ Release from JSR into Subspace, J_{SRrel}

$$J_{\text{SRrel}} = (P_{O1} + P_{O2}) \frac{[\text{Ca}^{2+}]_{\text{JSR}} - [\text{Ca}^{2+}]_{\text{ss}}}{\tau_{\text{rel}}} \quad (113)$$

$$\frac{dP_{C1}}{dt} = P_{O1} k_a^- - P_{C1} k_a^+ [\text{Ca}^{2+}]_{\text{ss}}^4 \quad (114)$$

$$\frac{dP_{O1}}{dt} = P_{C1} k_a^+ [\text{Ca}^{2+}]_{\text{ss}}^4 + P_{O2} k_b^- + P_{C2} k_c^- - P_{O1} (k_a^- + k_b^+ [\text{Ca}^{2+}]_{\text{ss}}^3 + k_c^+) \quad (115)$$

Table S10. Time constants of ion exchange between external bulk and cleft spaces.

Parameter	Definition	Value
$\tau_{\text{Na,bc}}$	τ of Na^{+} exchange between external bulk and cleft spaces	14.3 s
$\tau_{\text{K,bc}}$	τ of K^{+} exchange between external bulk and cleft spaces	10 s
$\tau_{\text{Ca,bc}}$	τ of Ca^{2+} exchange between external bulk and cleft spaces	24.7 s
